```

Problem 2

(a)

Let $N(t)$ be the number of cars arriving at a parking lot by time t , according to the proposed scenario, we can model $N(t)$ as a non-homogenous Poisson process. Such process has almost the same process as any other Poisson process, however, its rate is a function of time.

$N(t), t \in [0, \infty)$ is the non-homogenous Poisson process with rate $\lambda(t)$ where:

- $N(0) = 0$
- $N(t)$ has independent increments

We define 8:00 as $t = 0$ with the following integrable function and each unit of t equals to 1 hour:

$$\lambda(t) = \begin{cases} 100 & 0 \leq t \leq \frac{1}{2} \\ 600t - 200 & \frac{1}{2} < t \leq \frac{3}{4} \\ 400t - 50 & \frac{3}{4} < t \leq 1 \\ -500t + 850 & 1 < t \leq 1.5 \end{cases}$$

So,

$$E[N(t)] = \begin{cases} \int_0^t 100 dt = 100t & 0 \leq t \leq \frac{1}{2} \\ \int_{\frac{1}{2}}^t 600t - 200 dt + 50 = 300(t^2 - \frac{1}{4}) - 200(t - \frac{1}{2}) + 50 & \frac{1}{2} < t \leq \frac{3}{4} \\ \int_{\frac{3}{4}}^t 400t - 50 dt + 93.75 = 25(8t^2 - 2t - 3) + 93.75 & \frac{3}{4} < t \leq 1 \\ \int_1^t -500t + 850 dt + 168.75 = -50(5t^2 - 17t + 12) + 168.75 & 1 < t \leq 1.5 \end{cases}$$

Given that there is a limit of 150 vehicles:

$$E[N(t)] = \begin{cases} 100t & 0 \leq t \leq \frac{1}{2} \\ 300(t^2 - \frac{1}{4}) - 200(t - \frac{1}{2}) + 50 & \frac{1}{2} < t \leq \frac{3}{4} \\ 25(8t^2 - 2t - 3) + 93.75 & \frac{3}{4} < t < 0.94468 \\ 150 & t \geq 0.94468 \end{cases}$$

(b)

Luego de hacer las pruebas para $\lambda(t)$ obtenemos lo siguiente:

```
lambda = 139.6  
t = 0.91232  
# 8:44 AM
```

Por lo que $t = 0.91232$ horas (aproximadamente a las 8:54 de la mañana).

(c)

The following function simulates a non-homogenous poisson process from a homogenous poisson process:

```

non_hom_poisson <- function(fun,l,a,b,start=0) {
  # This function generates a non-homogenous poisson
  # process from a homogenous poisson process
  # PARAMS:
  # fun:   if the non-homogenous poisson process has
  #        multiple functions per time subinterval
  #        this parameters represents such function
  # l:     lambda for the homogenous poisson process
  # a:     lower bound for the time subinterval
  # b:     upper bound for the time subinterval
  # start: this parameter is used to keep track of
  #        the process count.

  # We generate the homogenous poisson process
  # arrival times
  val <- rpois(1,l*(b-a))
  intervals <- (b-a) * sort(runif(val)) + a

  # Non-homogenous poisson process
  evs <- length(intervals) # lenght of arrival times
  nh_val <- 0 + start # start of the event count
  nh_intervals <- c() # arrival times for the NHPP
  for (i in 1:evs) {
    if (runif(1) < fun(intervals[i])/l) {
      # only including intervals from the HPP which
      # match with fun(intervals[i])/l probability
      nh_intervals <- c(nh_intervals, intervals[i])
      nh_val <- nh_val+1 # adding one to the event count
    }
  }
  nh_events <- seq(1+start,nh_val,1) # events since the previous group
  return(list(arrival_times=nh_intervals, events=nh_events))
}

```

```

simulation <- function(iters, functions, lambdas, ints) {
  # This function simulates from the NHPP
  # iters:      number of iterations to plot and add to the list of
  #             dataframes
  # functions:  list of functions corresponding to the lambda function
  # lambdas:    list of lambdas for each subinterval
  # ints:      lists of vectors of 2 elements each containing the intervals
  #             that correspond to each element of lambdas and functions lists
  p <- list()
  for (i in 1:iters) {
    maximum <- 0 # start for the next NHPP simulation to continue count
    arr_times <- c() # arrival times
    events <- c() # event counts
    for (k in 1:4) {
      int <- non_hom_poisson(lambda_funs[[k]], lambdas[[k]],
                            ints[[k]][1], ints[[k]][2],
                            start=maximum)
      maximum <- max(int$events) # remembering last event count
      arr_times <- c(arr_times, int$arrival_times)
      events <- c(events, int$events)
    }
    p[[i]] <- data.frame(arrival_times=arr_times, events=events)
    # plots
    if (i == 1) {plot(arr_times, events, cex=0.5, pch='.',
                      col=randomColor(), xlim=c(0,1.5),
                      ylim=c(0,150))}
    lines(arr_times, events, col=randomColor())
  }
  return(p)
}

```

```
data <- simulation(1000, lambda_funs, lambdas, ints)
```

```
ratio <- 0
for (i in 1:length(data)) {
  df <- data.frame(data[[i]])
  cnt <- df %>% filter(arrival_times < 0.91232 & events >= 150) %>% dplyr::count()
  if (cnt[1] >= 1) {
    ratio <- ratio + 1
  }
}
```

```
ratio/1000
#> [1] 0.226
```

Problem 3

(a)

Our infinitesimal generator is the following:

$$Q = \begin{pmatrix} -\lambda & \lambda & 0 & 0 & \dots \\ \mu & -(\lambda + \mu) & \lambda & 0 & \dots \\ 0 & 2\mu & -(2\mu + \lambda) & \lambda & \dots \\ \vdots & \vdots & \vdots & \vdots & \ddots \end{pmatrix}$$

(b)

We solve the following system:

$$\begin{cases} \sum_{i=1}^{\infty} \pi_i = 1 \\ \lambda \pi_0 = \mu \pi_1 \\ \lambda \pi_1 = 2\mu \pi_2 \\ \vdots \\ \lambda \pi_{n-1} = 2\mu \pi_n \\ \vdots \end{cases}$$

First we have:

$$\begin{aligned} \pi_1 &= \frac{\lambda \pi_0}{\mu} \\ \pi_2 &= \frac{\lambda^2 \pi_0}{2\mu^2} \\ \pi_3 &= \frac{\lambda^3 \pi_0}{2^2 \mu^3} \\ &\vdots \\ \pi_n &= \frac{\lambda^n \pi_0}{2^{n-1} \mu^n} \\ &\vdots \end{aligned}$$

Then:

$$\sum_{i=0}^{\infty} \pi_i = \pi_0 + \frac{\lambda \pi_0}{\mu} + \frac{\lambda^2 \pi_0}{2\mu^2} + \dots + \frac{\lambda^n \pi_0}{2^{n-1} \mu^n} + \dots = 1$$

And so factoring π_0 we get:

$$\pi_0(1 + \frac{\lambda}{\mu} + \frac{\lambda^2}{2\mu^2} + \dots) = \pi_0(1 + \sum_{i=1}^{\infty} \frac{1}{2^{i-1}} (\frac{\lambda}{\mu})^i)$$

Then multiplying $\frac{2}{2}$ to the summation:

$$\pi_0(1 + \frac{2}{2} \sum_{i=1}^{\infty} \frac{1}{2^{i-1}} (\frac{\lambda}{\mu})^i)$$

$$= \pi_0(2 \sum_{i=0}^{\infty} (\frac{\lambda}{2\mu})^i - 1)$$

$$\pi_0(2(\frac{1}{1 - \frac{\lambda}{2\mu}}) - 1) = 1$$

$$\pi_0 = \frac{1}{2(\frac{1}{1 - \frac{\lambda}{2\mu}}) - 1}$$

⋮

$$\pi_n = \frac{\lambda^n}{2^{n-1}\mu_n\pi_0} \frac{1}{2(\frac{1}{1-\frac{\lambda}{2\mu}})-1}$$

finally:

$$\pi_n = \frac{1}{2^{n-1}} \left(\frac{\lambda}{\mu}\right)^n \pi_0$$

The infinite sum converges when $|\frac{\lambda}{2\mu}| < 1$ in which case the stationary distribution P exists.

Then:

$$L = \sum_{n=0}^{\infty} \pi_n * n$$

Using the following sum:

$$\sum_{i=0}^{n-1} ia^i = \frac{a - na^n + (n-1)a^{n+1}}{(1-a)^2}$$

As n approaches infinity:

$$\sum_{i=0}^{\infty} ia^i = \frac{a}{(1-a)^2}$$

We get the following:

$$L = \pi_0 [1 + \sum_{n=0}^{\infty} \left(\frac{\lambda}{\mu}\right)^n * \frac{n}{2^{n-1}}]$$

$$L = \pi_0 [1 + 2 \sum_{n=0}^{\infty} \left(\frac{\lambda}{2\mu}\right)^n * n]$$

$$L = \pi_0 [1 + 2 \frac{\frac{\lambda}{2\mu}}{(1-\frac{\lambda}{2\mu})^2}]$$

(c)

Let's consider the probabilities conditioned on the number of customers in the system that are present once our specific subject l gets into the system.

If there are no other customers when l gets into the system, there is no chance of overtaking.

$$P(N^{OV} = 0 | N^{PR} = 0) = 1$$

With N^{OV} being the number of customers that l overtakes and N^{PR} the number of customers present in the system (queing) when l gets in the system.

If $N^{PR} = 1$, then l can overtake only 1 customer, if the time it takes to be served is shorter than the time it takes the other customers to be served. Because of the memoryless property we can assert the following:

$$P(N^{OV} = 0 | N^{PR} = 1) = \frac{\mu}{\mu + \mu} = \frac{1}{2}$$

Actually, in general:

$$P(N^{OV} = k | N^{PR} = n) = \frac{1}{n+1}, n \leq c-1, k = 0, 1$$

As in this case $c=2$, our l subject can't overtake more than one customer.

Now, if $n \geq c$, that is, l has to get in queue and wait to be served. When l gets served, there is also one more customer getting served. Because, again, of the memoryless property.

$$P(N^{OV} = k | N^{PR} = n) = \frac{1}{c}, n = c, k = 0, 1$$

In our case, it does not matter how many customers are in the system, the probability of overtaking, conditioned to the number of customers already in the system, is $\frac{1}{2}$.

Now, using Bayes' theorem and the total probability rule, we can find the probability of l overtaking another customer.

$$\begin{aligned}
P(A|B) &= \frac{P(A \cap B)}{P(B)} \\
\frac{1}{2} \sum_{i=1}^{\infty} \pi_i &= \frac{1}{2} \sum_{i=1}^{\infty} \left(\frac{1}{2^i-1}\right) \left(\frac{\lambda}{\mu}\right)^i \pi_0 \\
&= \sum_{i=1}^{\infty} \left(\frac{\lambda}{2\mu}\right)^i \pi_0 = \left(\sum_{i=0}^{\infty} \left(\frac{\lambda}{2\mu}\right)^i - 1\right) \pi_0 \\
&= \left(\frac{1}{1-\frac{\lambda}{2\mu}} - 1\right) \pi_0 = \frac{1}{2\left(\frac{1}{1-\frac{\lambda}{2\mu}} - 1\right)} \left(\frac{1}{1-\frac{\lambda}{2\mu}} - 1\right) \\
&= \frac{1}{1-\frac{\lambda}{2\mu}} - 1 = \frac{1-(1-\frac{\lambda}{2\mu})}{1-\frac{\lambda}{2\mu}} = \frac{\frac{\lambda}{2\mu}}{1-\frac{\lambda}{2\mu}} \\
&= 2\left(\frac{1}{1-\frac{\lambda}{2\mu}}\right) - 1 = \frac{2}{1-\frac{\lambda}{2\mu}} - 1 = \frac{2-(1-\frac{\lambda}{2\mu})}{1-\frac{\lambda}{2\mu}} \\
&= \frac{1+\frac{\lambda}{2\mu}}{1-\frac{\lambda}{2\mu}}
\end{aligned}$$

Then:

$$\frac{\frac{\lambda}{2\mu}}{1+\frac{\lambda}{2\mu}} = \frac{\frac{\lambda}{2\mu}}{\frac{2\mu+\lambda}{2\mu}} = \frac{\lambda}{2\mu+\lambda}$$

So then we get:

$$P(N^{OV} = k) = \frac{\lambda}{2\mu+\lambda}, k = c-1 = 1$$

(d)

We define the following function to simulate the queueing system:

```

q <- function(customers, l, m) {
  exp_at <- rexp(customers,l)
  ArrivalTimes <- rep(0,customers)
  ArrivalTimes[1] <- exp_at[1]
  for (i in 2:customers) {
    ArrivalTimes[i] <- ArrivalTimes[i-1] + exp_at[i]
  }
  ServiceTimes <- rexp(customers, m)
  ExitTimes <- rep(0,customers)
  ExitTimes[1:2] <- ServiceTimes[1:2]
  for (i in 3:customers) {
    SortedTimes <- sort(ExitTimes[1:(i-1)], decreasing=T)
    if (ArrivalTimes[i] < SortedTimes[2]) {ExitTimes[i] <- SortedTimes[2] + ServiceTimes[i]}
    else {ExitTimes[i] <- ArrivalTimes[i] + ServiceTimes[i]}
  }
  times <- data.frame(arrival=ArrivalTimes,
                      exit=ExitTimes,
                      service=ServiceTimes)
  return(times)
}

number_of_customers <- 8500
times <- q(number_of_customers, l=0.4, m=0.25)
plot(times$exit)

```

```
last_arrival_time <- times$arrival[length(times$arrival)]
sum(times$exit > last_arrival_time)
#> [1] 5
```

```
nb.pe=numeric(length=length(t))
for (i in 1:length(times$service)){
  nb.pe[i]=length(which(times$arrival<times$service[i]&times$exit>times$service[i]))
}
```

(e)

We define the following function to calculate the overtaking probability:

```
d <- function(customers, ot_prob, queue, ExitTimes) {
  for (i in queue:(customers - queue)) {
    ot_prob <- ot_prob + sum(ExitTimes[i] < ExitTimes[1:(i-1)])
  }
  r <- customers-2*queue
  ot_prob <- ot_prob/r
  return(ot_prob)
}
```
